- Standard Vocabularies
- Linked Data
- RDFa
- Applications

Great, and now?

Person	Job
Elvis	singer

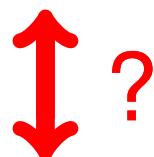

Data formats are incompatible

Person	Job
Elvis	singer

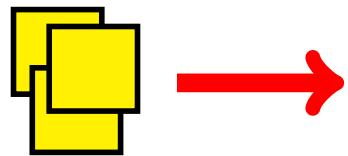

Person	Occupation
Elvis P.	singer

<person>
<occupation>

Devices are often incompatible

Person	Job
Elvis	singer

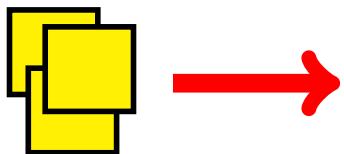

Person	Occupation
Elvis P.	singer

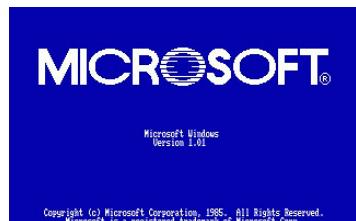

<person>
<occupation>

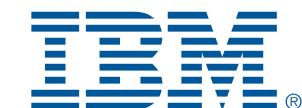

Companies are often incompatible

Person	Job
Elvis	singer

Person	Occupation
Elvis P.	singer

<person>
<occupation>

Where do we need interaction?

- Booking a flight

Interaction between office computer, flight company, travel agency, shuttle services, hotel, my calendar

- Finding a restaurant

Interaction between mobile device, map service, recommendation service, restaurant reservation

- Buying stuff in a supermarket

Netto App, iPhone, bank account, mail account, Netto homepage

[>more](#)

Where do we need interaction?

- Web service composition

Interaction between client and Web services
and Web services themselves

- Intelligent home

Fridge knows my calendar, orders food if
I am planning a dinner

- Intelligent cars

Car knows my schedule, where and when
to get gas, how not to hit other cars, what
are the legal regulations

[>more](#)

Where do we need interaction?

- Adding data to a database

From XML files, from other databases

- Merging data after company mergers

(e.g. Apple buys Microsoft)

Different terminology has to be bridged,
accounts to be merged

- Merging data in research

e.g. biochemical, genetic , pharmaceutical research data

Def: Semantic Web

Idea: We need an infrastructure that allows computers to “understand” their data.

想法：我们需要一个基础设施，让计算机“理解”他们的数据。

This infrastructure shall

- allow machines to process data from others
- ensure interoperability between schemas, devices and organizations
- allow data to describe data
- allow machines to reason on the data
- allow machines to answer semantic queries

这个基础设施应

- 允许机器处理来自其他人的数据
- 确保模式之间的互操作性，设备和组织
- 允许数据描述数据
- 允许机器推理数据
- 允许机器回答语义查询

This is what the Semantic Web aims at

这是语义网的目标

语义网络是万维网的一个不断发展的扩展，其中数据以一种标准化的语义格式提供。

The **Semantic Web** is an evolving extension of the World Wide Web, in which data is made available in one standardized semantic format.

The Semantic Web

- Knowledge Representation
- URIs
- Standard Vocabularies
- Linked Data
- RDFa
- Applications

Def: RDF

RDF (Resource Description Framework) is a knowledge representation based on

- entities
- classes
- binary relations
- labels

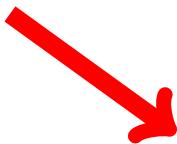

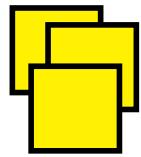

RDF (资源描述框架) 是一种基于知识表示的

- 实体
- 课程
- 二元关系
- 标签

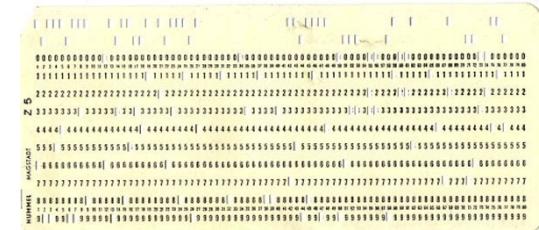

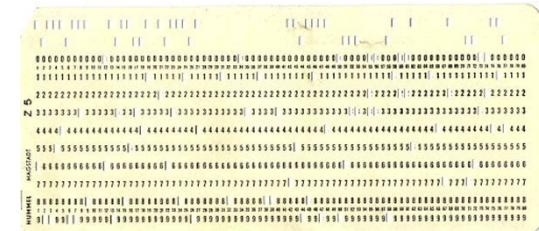

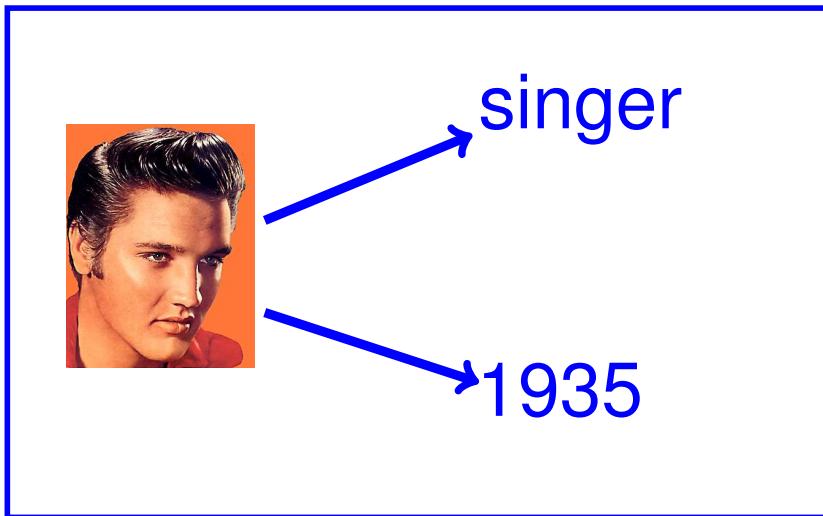

这恰巧是我们在整个演讲中使用的表示。

... which is coincidentally the representation that we have been using throughout this lecture.

Knowledge Representation in SW

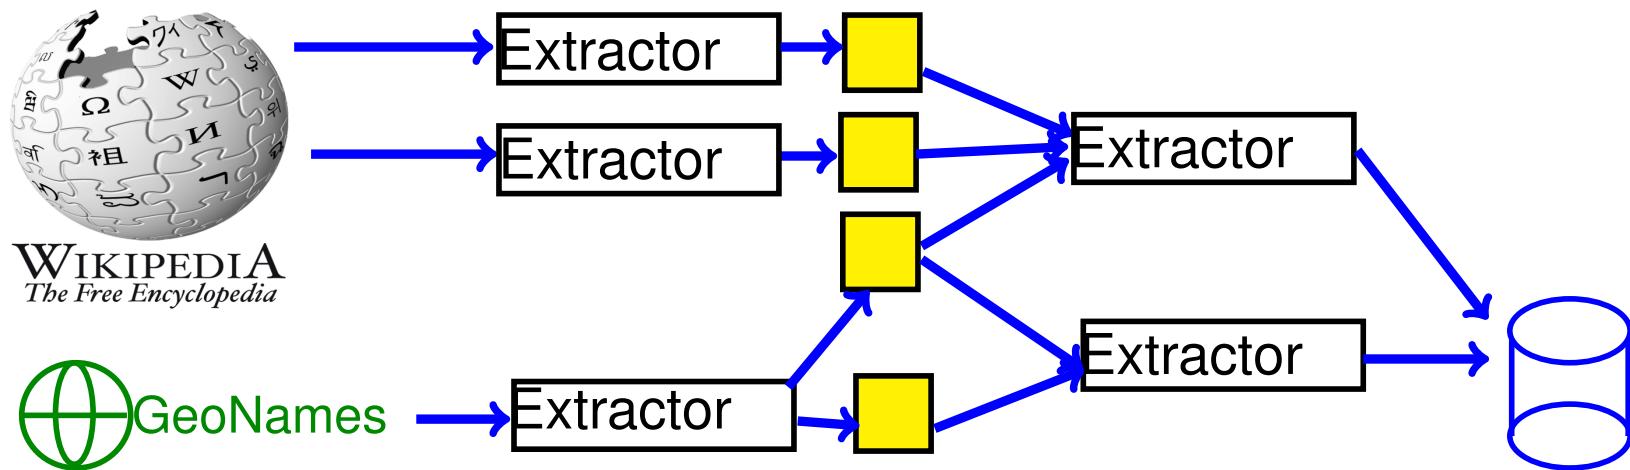

Person	Job	Birth
Elvis	singer	1935

<person>

<occupation>

Example: YAGO

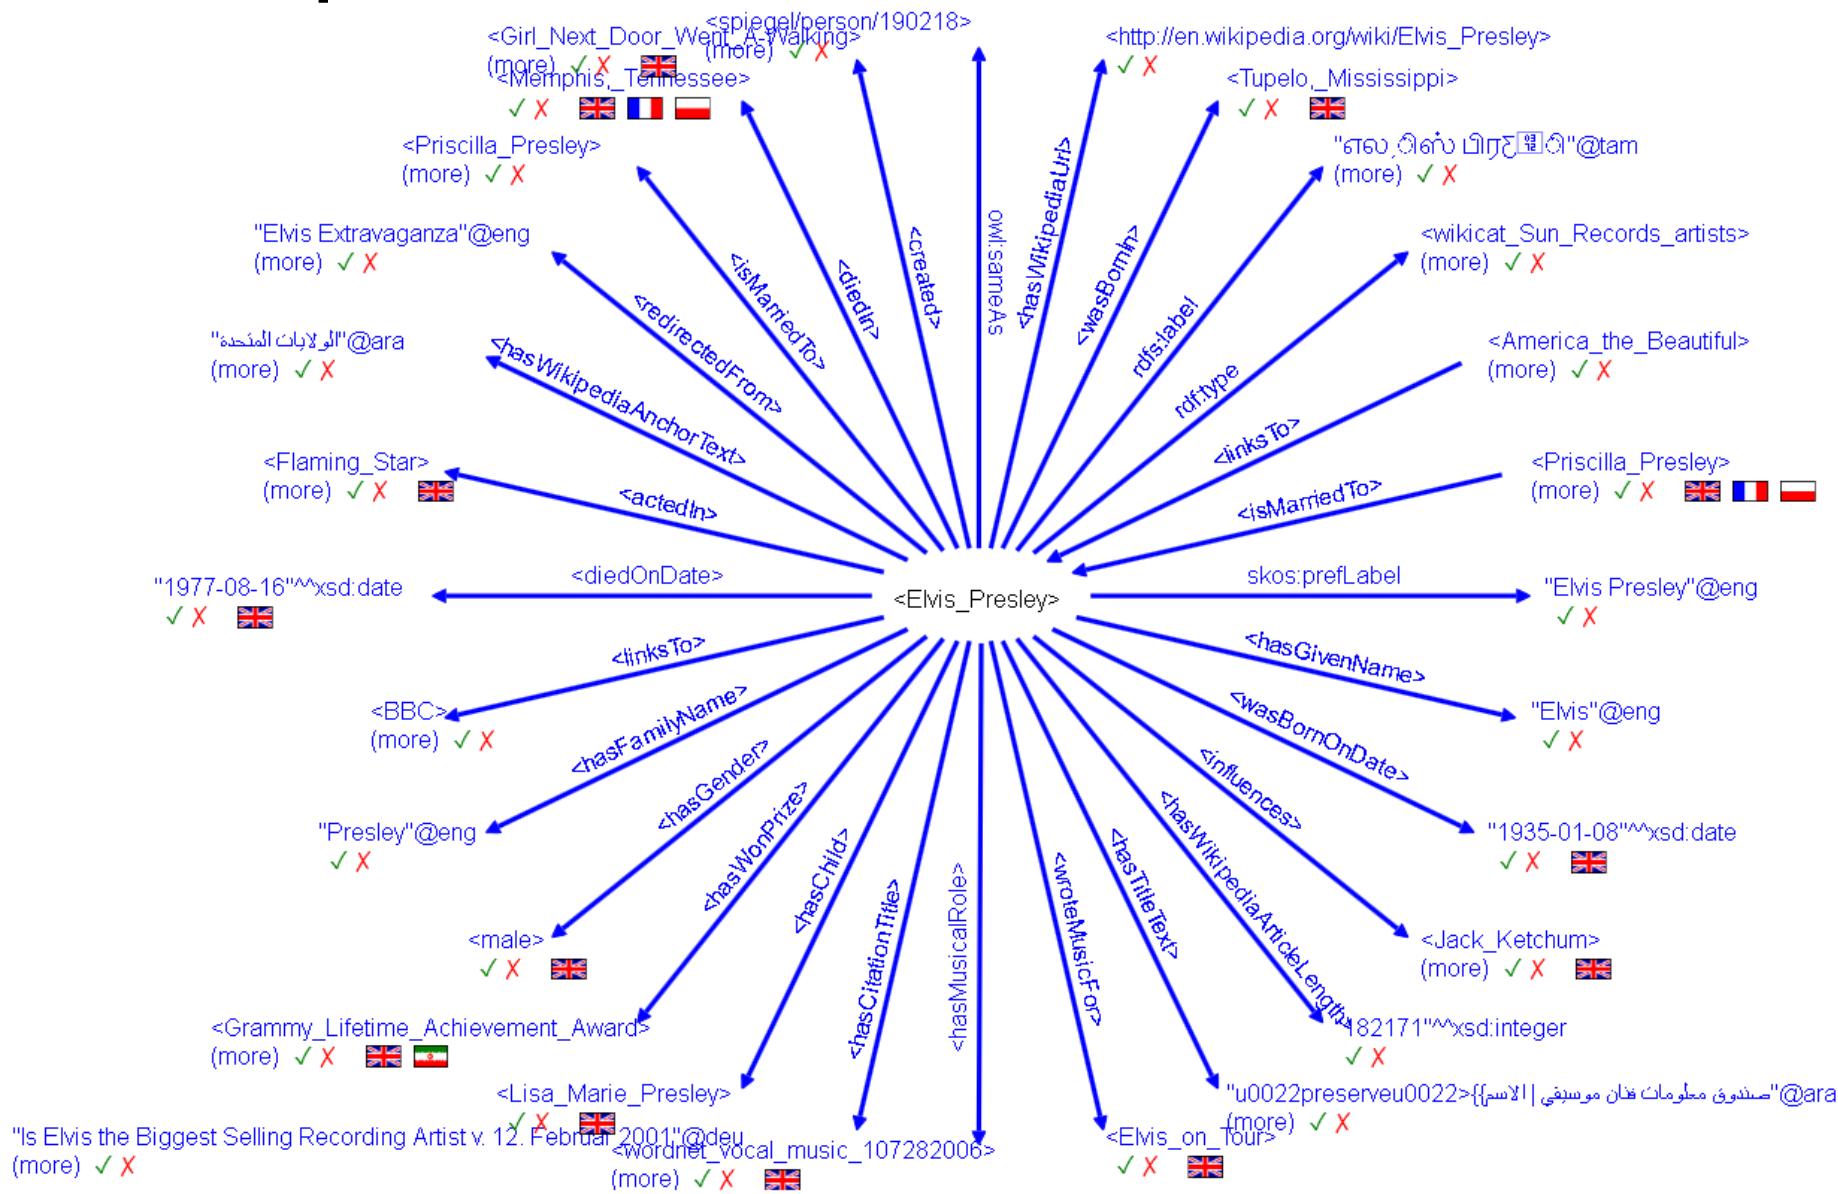

YAGO is a knowledge base that was automatically constructed from Wikipedia and other sources:

- 10m entities, 100m facts
- 95% accuracy
- 1700+ citations on WWW 2007 paper
- 10 languages
- used by IBM Watson, Bloomberg, DBpedia,...

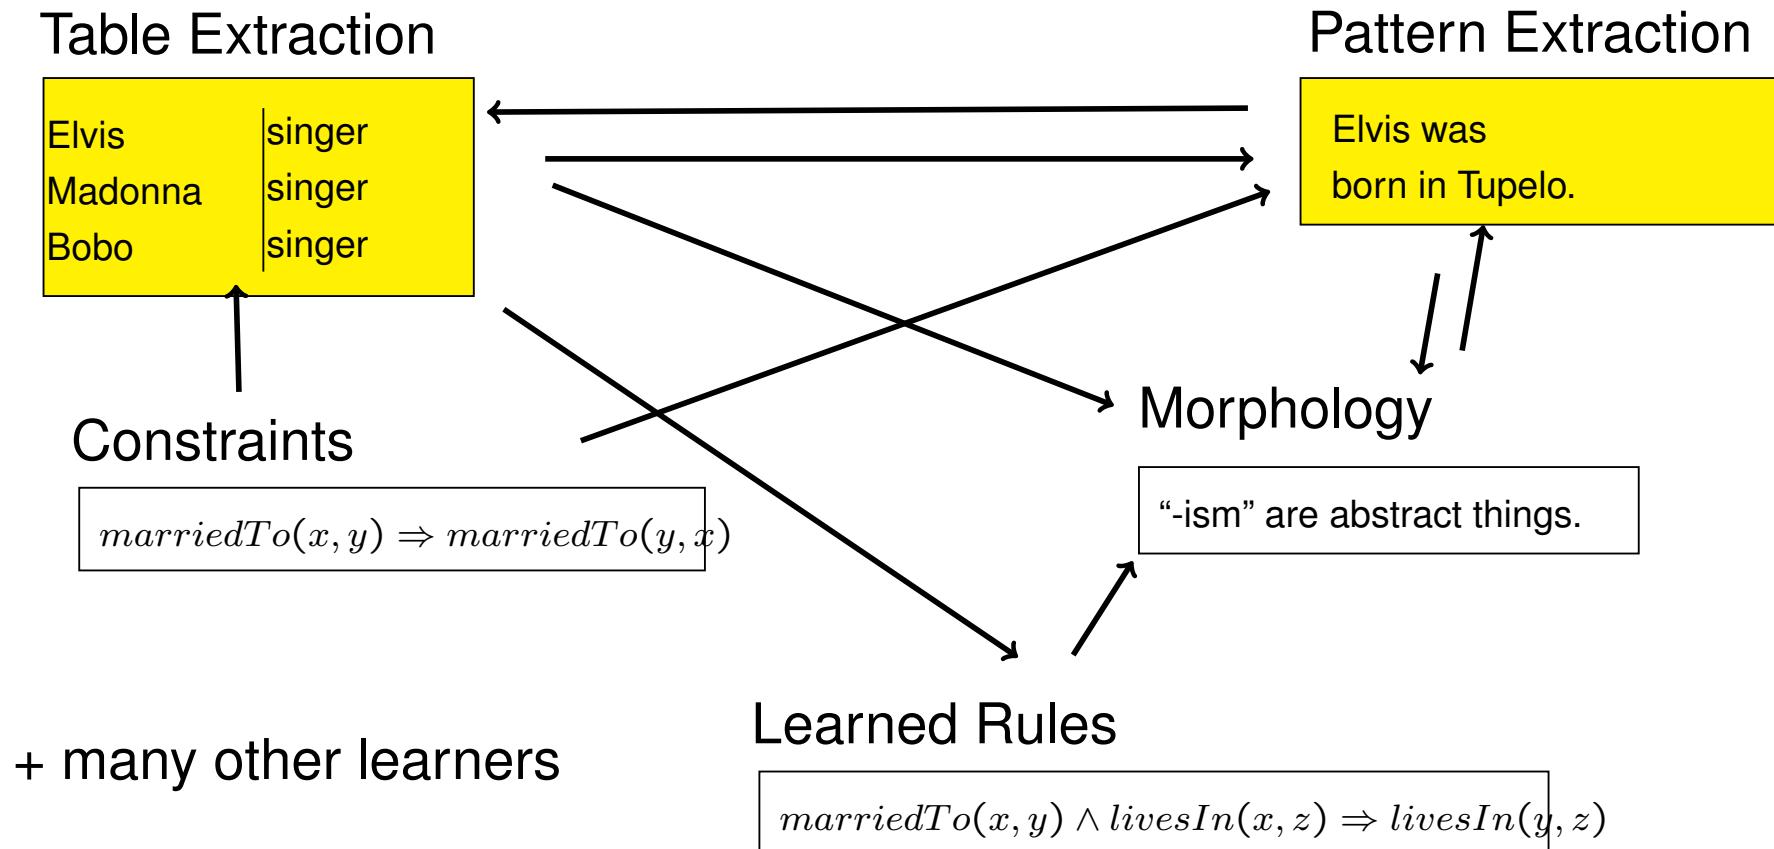

Example: YAGO about Elvis

Example: NELL / Read The Web

NELL (Never Ending Language Learner) is an information extraction project at Carnegie Mellon University. It couples several learners.

NELL (Never Ending Language Learner) 是卡内基梅隆大学 (Carnegie Mellon University) 的一个信息抽取项目。它结合了几个学习者。

Example: NELL about “MacBook”

categories

- product(100.0%)

About: [Elvis Presley](#) [Goto Sponge](#) [NotDi](#)

An Entity of Type : [yago:WikicatAmericanPeopleOfScotch](#)

Type: [yago:WikicatAmericanPeopleOfScotch-IrishDescent](#) ▾

Elvis Aaron Presley (January 8, 1935 – April 12, 1977) was an American singer and actor who became one of the most significant cultural icons of the 20th century. He was born in Tupelo, Mississippi, as a twin to his brother, Gladys and Vernon Presley. His music career began there in 1948, when he joined his father's band, the Memphis-based Blue Moon Boys.

The Semantic Web

- Knowledge Representation
- URIs
- Standard Vocabularies
- Linked Data
- RDFa
- Applications

Globally identifying entities

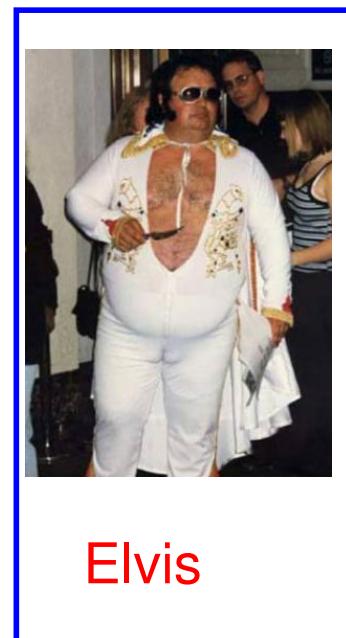

KB1

KB2

KB3

KB4

Def: Namespace / Qualified Name

A **namespace** is a named set of (so-called local) names.

[Wikipedia/Namespace](#) 命名空间是一个命名的（所谓的本地）名称集合。

namespace: KB1

contains local names: Elvis, Priscilla, Lisa

namespace: KB2

contains local names: Elvis, Michael

A **qualified name** consists of a namespace name and a local name.

KB1:Elvis

KB1:Priscilla

KB2:Elvis

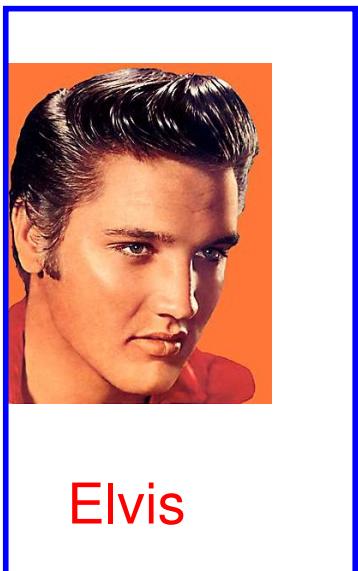

Examples

What if KBs have the same name?

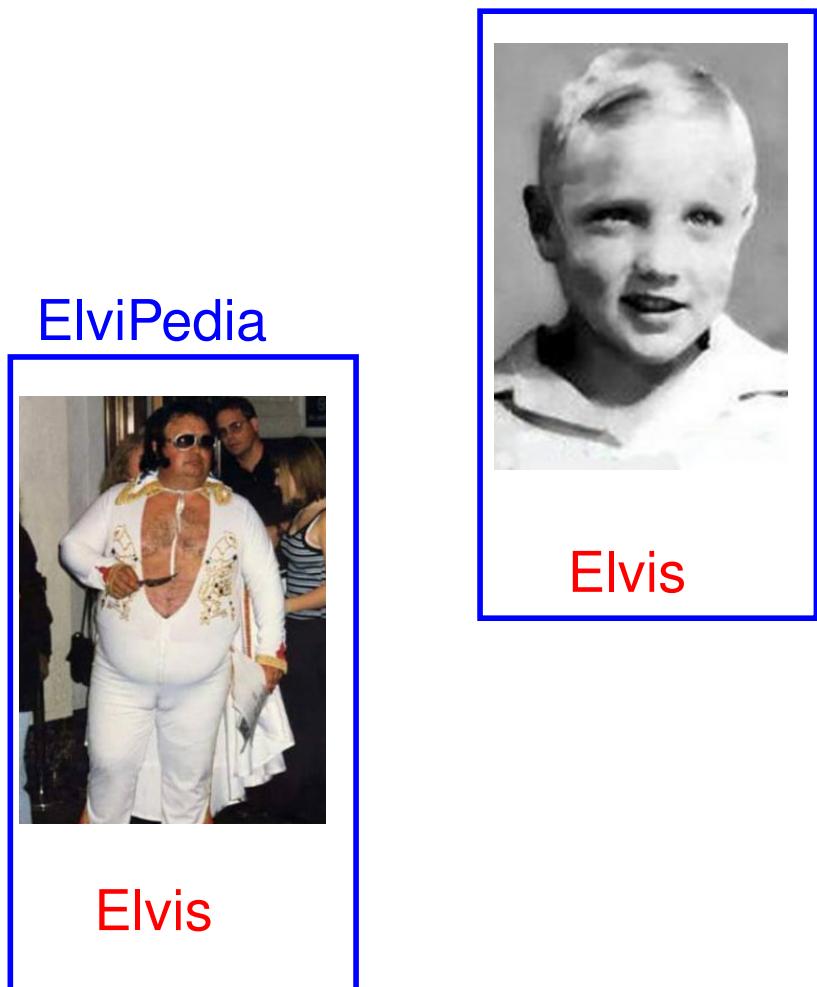

ElvisKB

ElvisKB

ElviPedia

Def: URI

A **URI** (Uniform Resource Identifier) is a string that follows the syntax

<scheme name> : <hierarchical part> [? <query>] [# <fragment>]

Examples:

- URLs

<http://elvis.com/biography.html#Birth>

- File identifiers

<file:///c:/users/elvis/tripToMoon.txt>

- FTP

<ftp://elvis@nsa.gov>

- MailTo

<mailto:him@elvis.com?subject=Where%20%are%20you>

Not all URIs are dereferenceable

A URI per se is just a string.

It is not necessarily connected to a Web page.

<http://elvis.is/dead>

Not all URIs are dereferenceable

A URI per se is just a string.

It is not necessarily connected to a Web page.

<http://elvis.is/dead>

Error 404

Sorry - this URL could not be found

You probably typed nonsense.

We assign a URI to each KB

ElviPedia: <http://elvis-alive.org/>

ElviPedia': <http://elvipedia.com/>

ElvisKB: <http://elvis.org/kb/>

YAGO: <http://yago-knowledge.org/>

Each of them
forms a
namespace.

URI of ElviPedia:

<http://elvis.org/kb/>

Name in that namespace:

[Priscilla](#)

Qualified name:

[\(again a URI\)](http://elvis.org/kb/Priscilla)

Namespaces

<http://elvis.is/king/of/sing>

World-wide unique
mapping to domain
owner

in the responsibility
of the domain owner

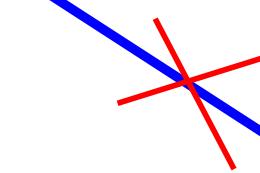

=> There should be no overlap

- a company can create URIs to identify its products
- an organization can assign sub-domains and each sub-domain can define URIs
- individual people can create URIs from their homepage
- people can create URIs from any URL for which they have exclusive rights to create URIs

URIs are never ambiguous

A URI always refers to one entity, never to more entities.

<http://kb.org/Priscilla>

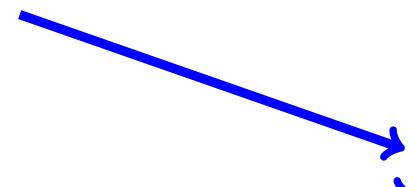

URIs can be synonymous

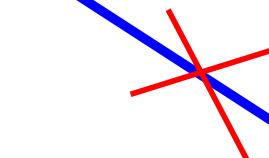

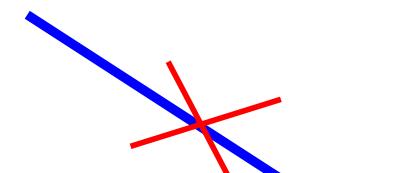

A URI always refers to one entity, never to more entities.

One entity can be referred to by several URIs.

<http://onto.org/Priscilla>

<http://kb.org/Priscilla>

Def: Base URI

A **base URI** is a URI relative to which URIs in the same document are interpreted.

@base <http://yago-knowledge.org/> .

<Elvis relative URI, interpreted wrt. base URI

=

<http://yago-knowledge.org/Elvis>

Def: Namespace prefix&CURIE

A **namespace prefix** is an abbreviation for the first part of a URI.

A prefix with a local name yields a **CURIE** (also:Qname).

@prefix dbp: <<http://dbpedia.org/>> .

dbp:Elvis ← CURIE (Compact URI)
= or QName (qualified name)
<<http://dbpedia.org/Elvis>>

Def: Turtle

Turtle (Terse RDF Triple Language) is a particular syntax for writing RDF facts.

Turtle can declare namespace prefixes and a base as follows:

`@prefix P: <URI> .`

`@base <URI> .`

see Example

A simple Turtle fact has the form

`URI—Curie URI—Curie URI—Curie—literal .`

Example:

`@prefix y: <http://yago-knowledge.org/>`

`y:Elvis y:loves y:Priscilla .`

`y:Priscilla y:loves <http://kb.org/cake>.`

`y:Elvis y:isCalled "The King" .`

Each line is a triple of 3 URIs. Each URI identifies an entity.

The URI in the middle identifies a relation entity.

Each URI can be given explicitly or as a Curie. The object can also be a literal.

Data types

Turtle allows attaching a **datatype** to a literal in the form

"literal"^^datatype

The datatype is given by a URI or Curie.

[see them](#)

It is common to use the XML datatypes

[xsd:boolean](#) true, false

[xsd:decimal](#) Arbitrary-precision decimal numbers

[xsd:integer](#) Arbitrary-size integer numbers IEEE floating-point

[xsd:double](#) 64-bit floating point numbers incl. Inf, 0, NaN

[xsd:float](#) 32-bit floating point numbers incl. Inf, 0, NaN

[xsd:date](#) Dates (yyyy-mm-dd) with or without timezone

[xsd:time](#) Times (hh:mm:ss.sss...) with or without timezone

[xsd:dateTime](#) Date and time with or without timezone

...

Summary: URIs & Turtle

- URIs are identifiers, often look like URLs

<http://sing.it/elvis>

- Curies abbreviate URIs

[y:Elvis](#)

- Turtle is a syntax for RDF facts

[`<http://kb.org/Elvis> y:sings y>AllShookUp .`](#)

The Semantic Web

- Knowledge Representation
- URIs
- Standard Vocabularies
- Linked Data
- RDFa
- Applications

Cross-referencing

A KB can make statements about entities defined in other KBs.

@prefix y: <<http://yago-knowledge.org/>>

@prefix d: <<http://dbpedia.org/>>

y:Priscilla y:loves d:MikeStone .

Standard vocabulary

A KB can define vocabulary that is used by other KBs.

y:Singer

- subclasses
- superclasses
- label
- ...

AlizéeKB

y:Singer

type

Def: RDF Vocabulary

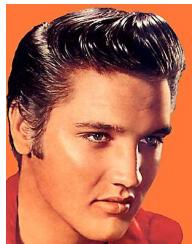

RDF is also a vocabulary (=KB) that defines basic notions of KB representation.

@prefix rdf: <<http://www.w3.org/.../rdf/>>

rdf:type, rdf:Property, rdf:Statement ...

see this KB

We can use notions from this KB:

rdf:type → y:Singer

Def: RDFS Vocabulary

RDFS is a vocabulary (=KB) that defines basic notions for class representation.

@prefix rdfs: <<http://www.w3.org/.../rdfs/>>

rdfs:label, rdfs:subClassOf,

rdfs:domain, rdfs:range,

rdfs:Class, rdfs:Resource

see this KB

see Example

Sharing vocabularies

Shared vocabularies mean

- shared work in defining entities
- inter-operability of KBs

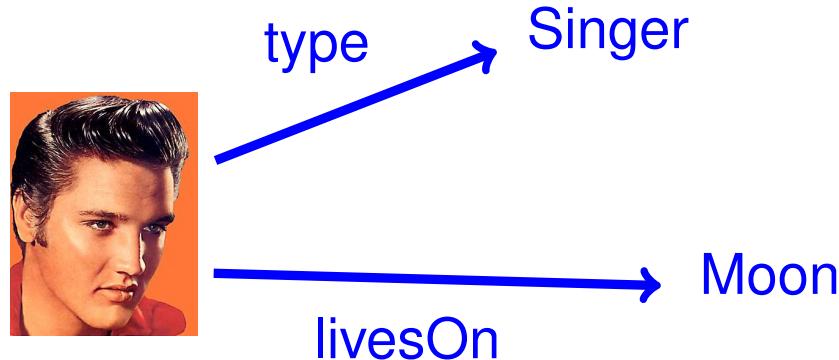

Some shared vocabularies have become standards on the Semantic Web. They have a standard namespace prefix. However, nothing prescribes the use of these vocabularies or prefixes.

```
@prefix rdf: <http://really.dumb.fellow.org/>
rdf:TheKing rdf:type rdf:monarch .
```

Task: Turtle & RDF

Write the following facts in Turtle,
using RDF vocabulary where possible.

URI of KB: <<http://whatyoushouldknow.org/>>

Start with

@prefix rdf: <<http://www.w3.org/1999/02/22-rdf-syntax-ns>>

More vocabularies

- Dublin Core (for describing documents)
<http://purl.org/dc/elements/1.1/>
- Schema.org (for Web content)
<http://schema.org>
- Creative Commons (types of licences)
<http://creativecommons.org/ns#>
- Facebook Open Graph (for Web content)
<http://ogp.me/>

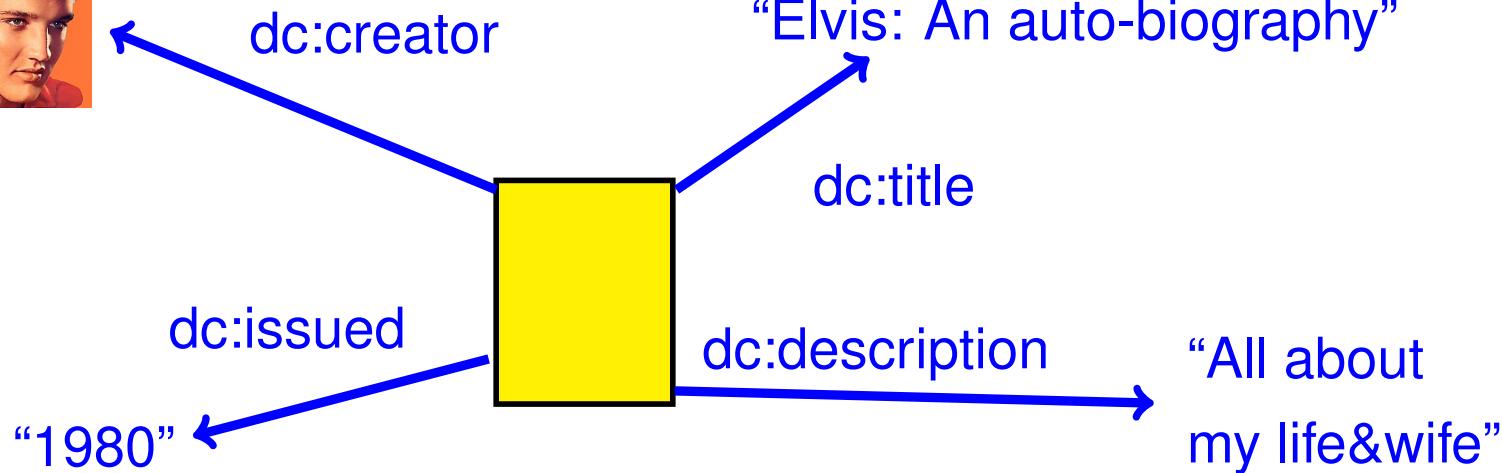

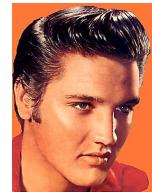

>more

Dublin Core

Dublin Core is a vocabulary (=KB) of terms (=entities) for describing documents.

dc:creator, dc:title, dc:format,
dc:MediaType, dc:language...

see this KB

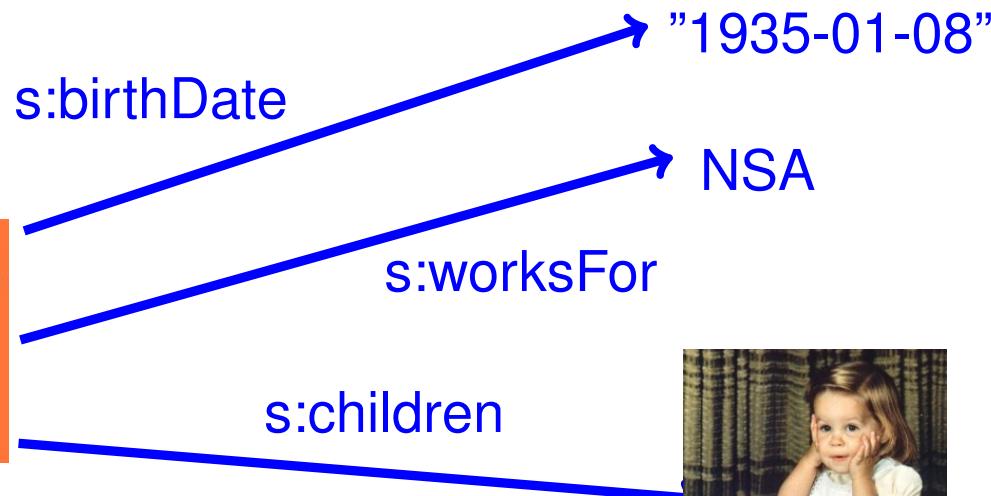

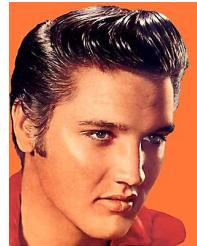

>more

Schema.org

Schema.org is a KB by Google, Yahoo & Microsoft for describing Web content.

s:Person, s:Movie, s:address,
s:follows, s:worksFor, ... see this KB

>more

Open Graph

Open Graph is a KB by Facebook for describing Web content.

[video:actor](#), [video:duration](#),
[book:author](#), [profile:gender](#), ...

[see this KB](#)

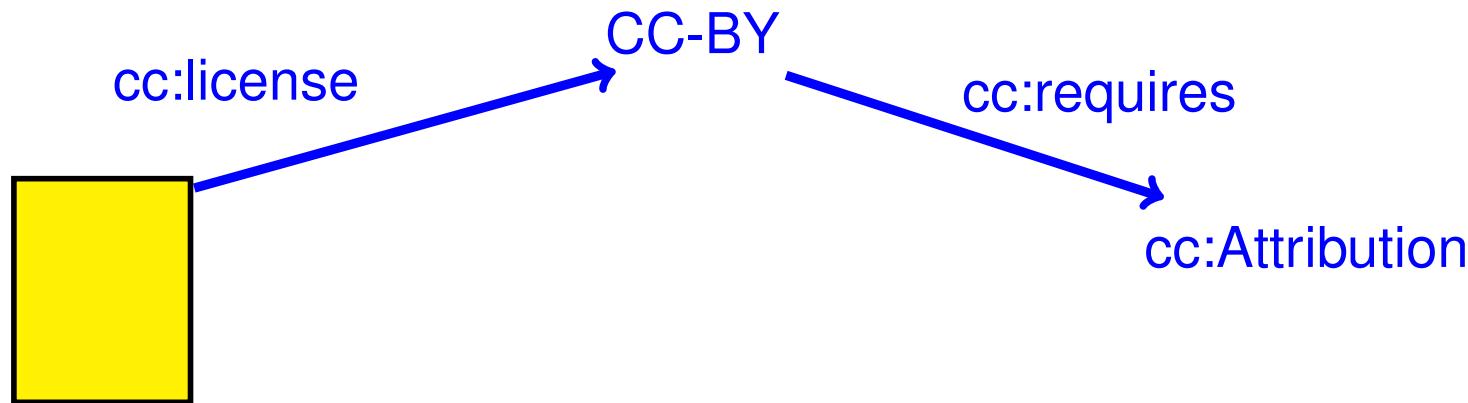

[>more](#)

Creative Commons

Creative Commons provides their vocabulary in RDF.

cc:license, cc:attributionName,
cc:permits, cc:Reproduction, ...

see this KB

Summary: Standard Vocabulary

- Vocabulary can be re-used across KBs
- This brings advantages such as less design effort, interoperability
- Some standard vocabularies have evolved

RDF, RDFS, schema.org

The Semantic Web

- Knowledge Representation
- URIs
- Standard Vocabularies
- **Linked Data**
- RDFa
- Applications

Def: Dereferenceable/Cool URI

A **dereferenceable URI** (also: Cool URI) is a URI that returns an RDF snippet if accessed on the Internet by an RDF client.

[W3C/Cool URIs](#)

<http://elvispedia.org/Elvis>

```
@prefix e: <http://elvispedia.org/>
e:Elvis e:sings e:aSong .
e:Elvis e:born e:Tupelo .
...
```

For this to work, the data has to be stored at the domain of the URI

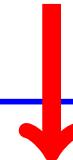

Cool URIs can be traversed

@prefix e: <<http://elvispedia.org/>>

@prefix d: <<http://dbpedia.org/>>

e:Priscilla e:loves d:MikeStone

...

<http://dbpedia.org/MikeStone>

@prefix e: <<http://dbpedia.org/>>

@prefix rdf: <<http://w3c.org/.../rdf>>

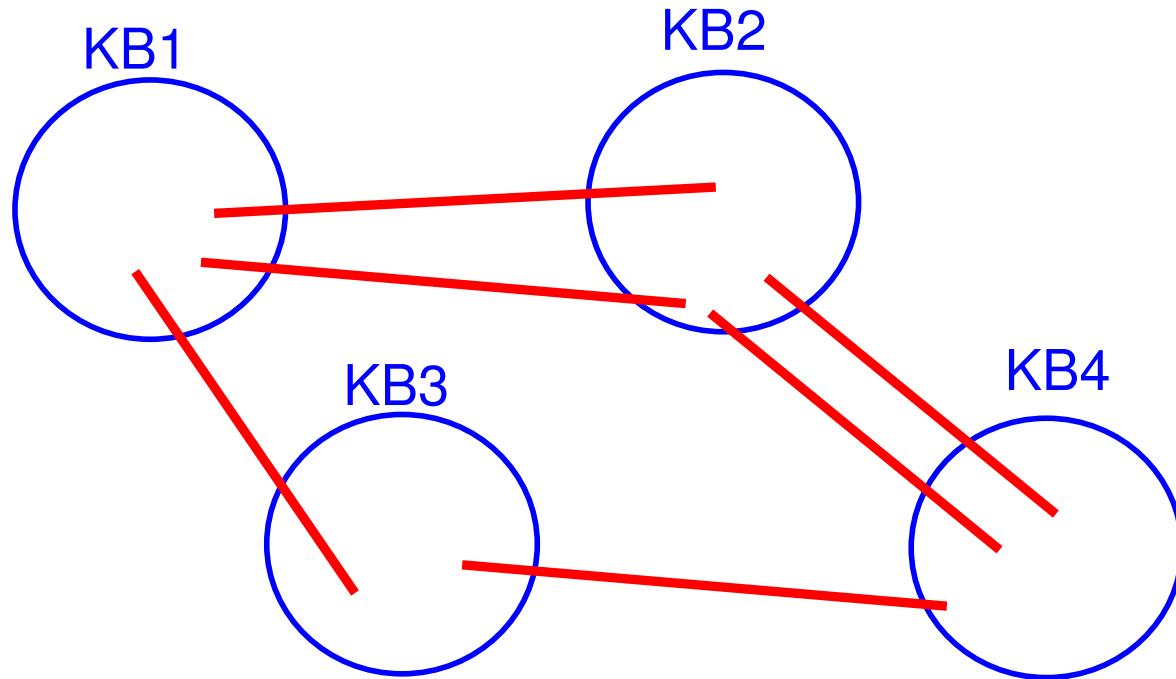

d:MikeStone rdf:type d:KarateClown

d:MikeStone d:livesIn d:LosAngeles

...

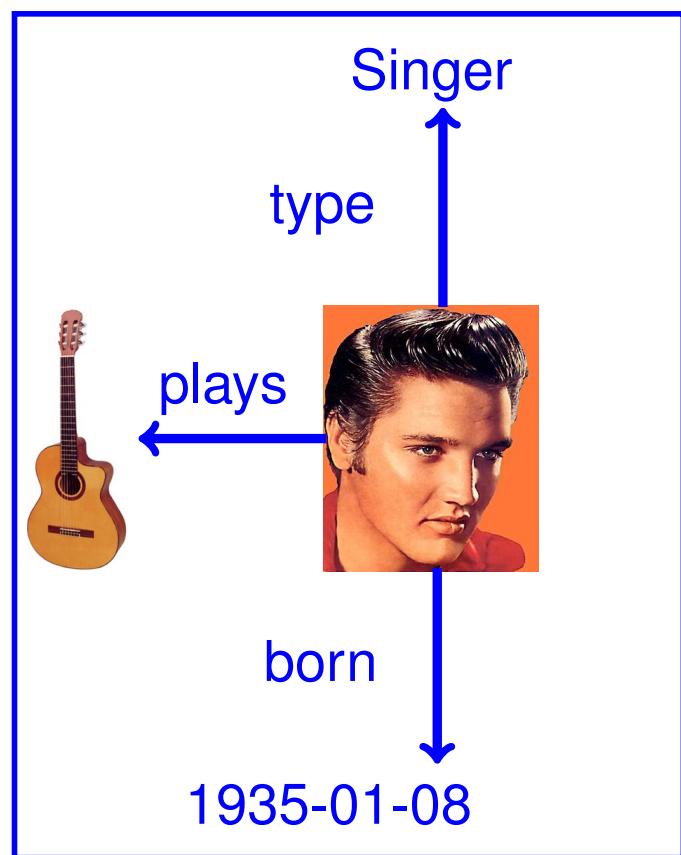

Cool URIs can be traversed

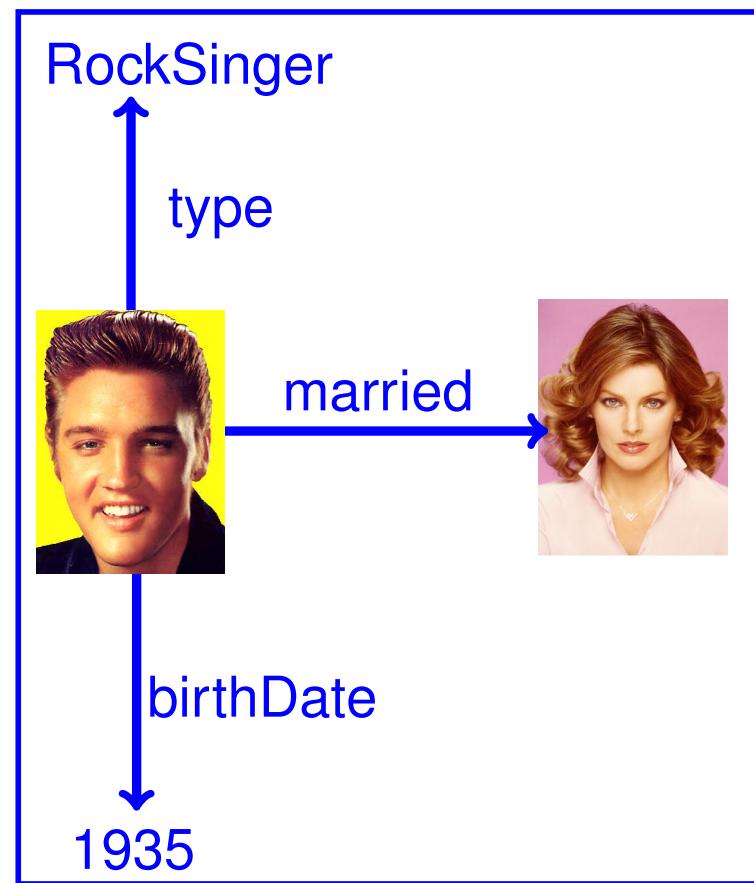

The standard vocabularies (RDF, RDFS, schema.org, Creative Commons, etc.) all provide dereferenceable URIs, as do many KBs.

[try it out](#)

Everybody can create KBs & URIs

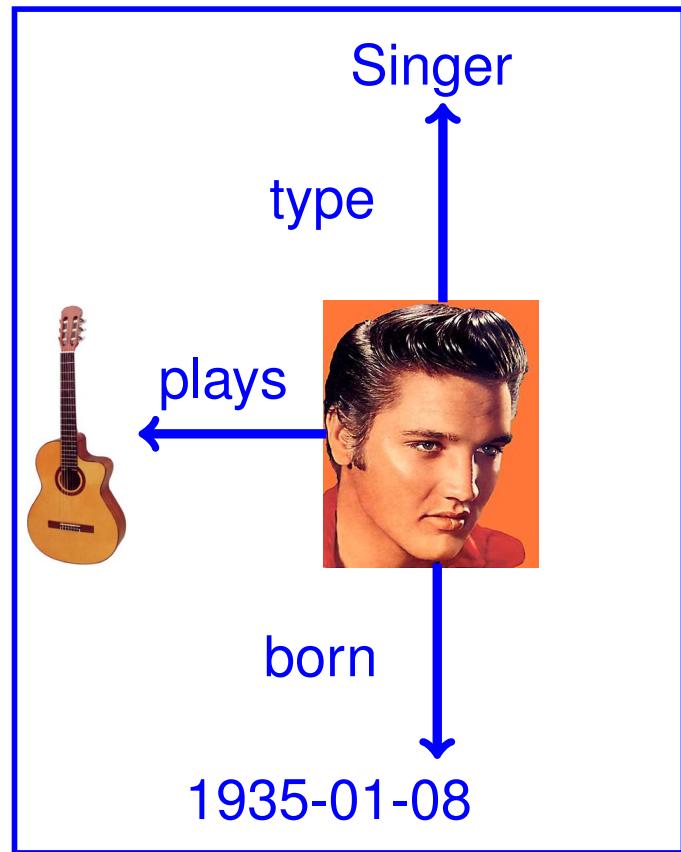

YAGO

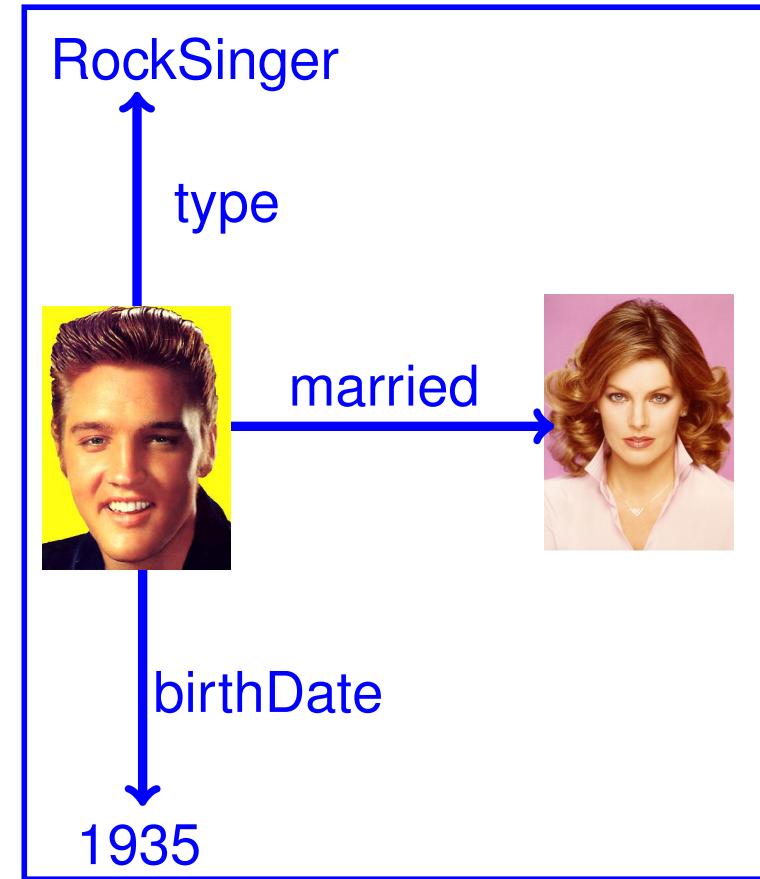

ElvisPedia

Distinct URIs => No use

Who is the spouse of the guitar player?

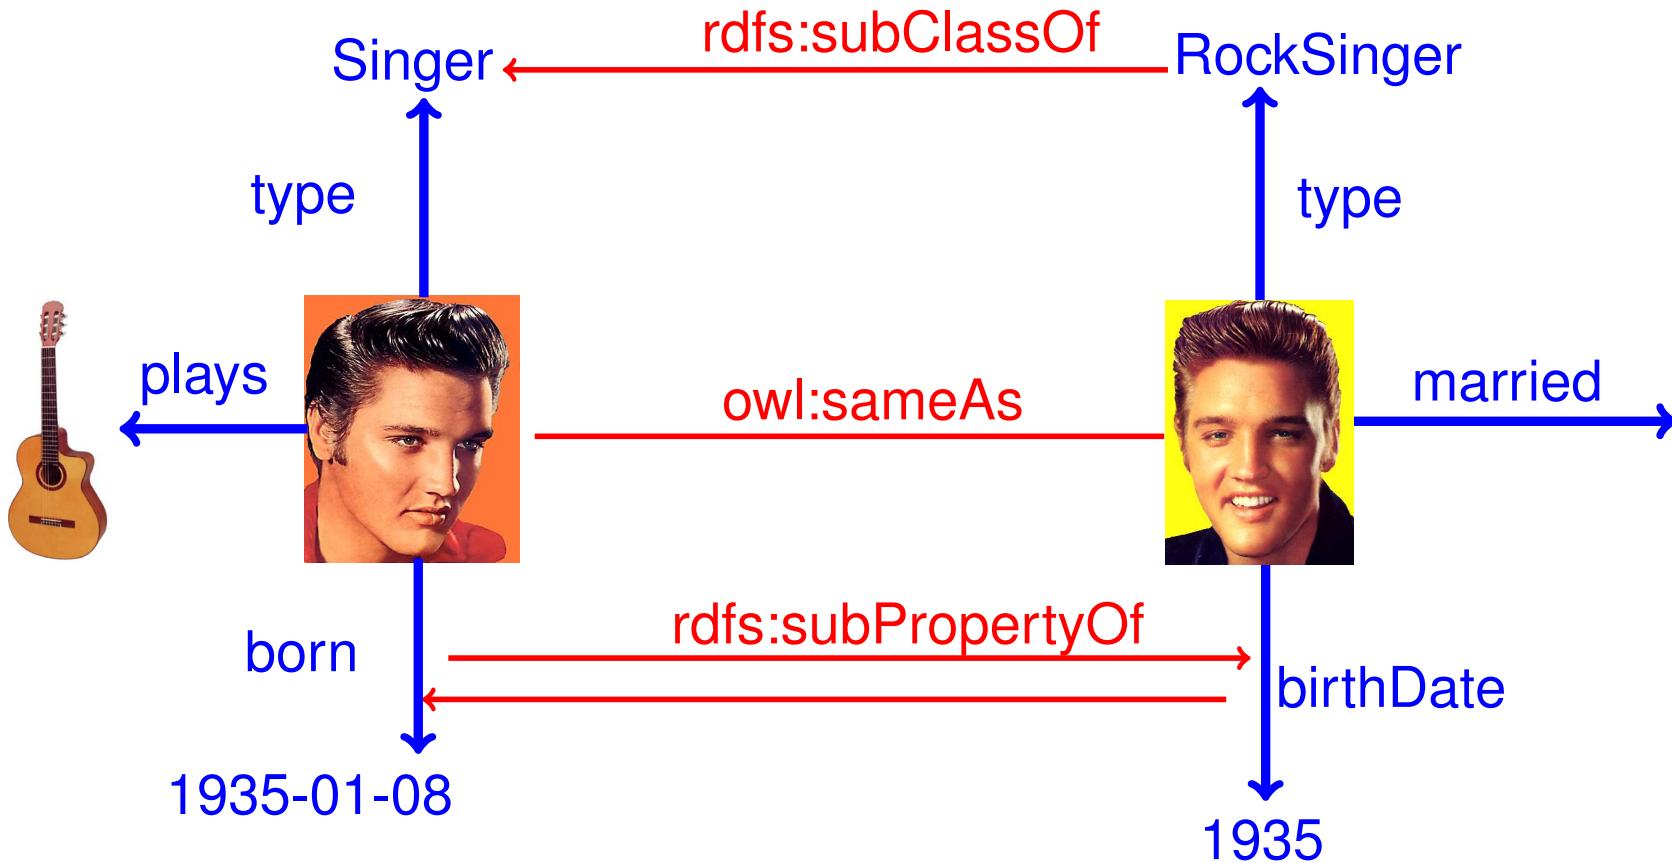

YAGO

ElvisPedia

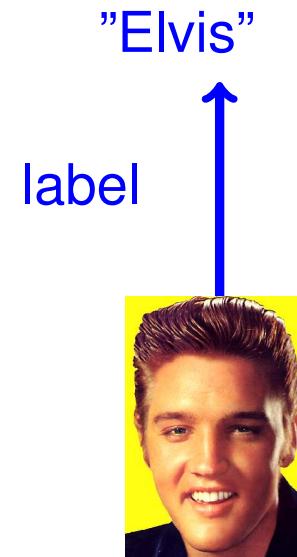

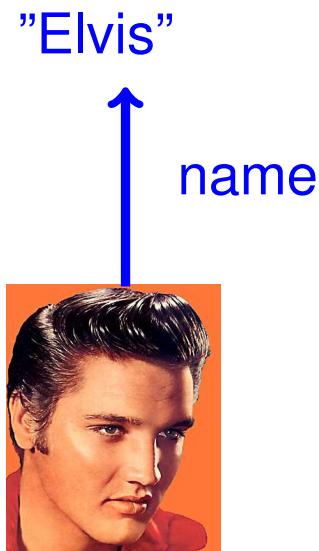

Def: Knowledge Base Alignment

KB alignment (also: KB mapping, KB linking) is the task of mapping the entities, classes, and relations of one KB to their pendants in the other.

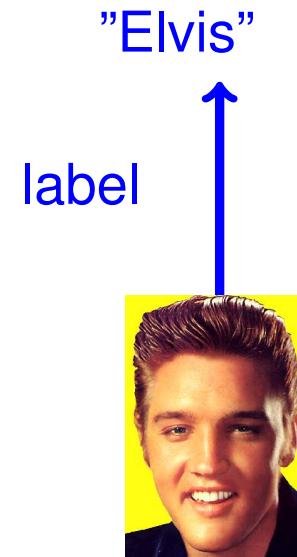

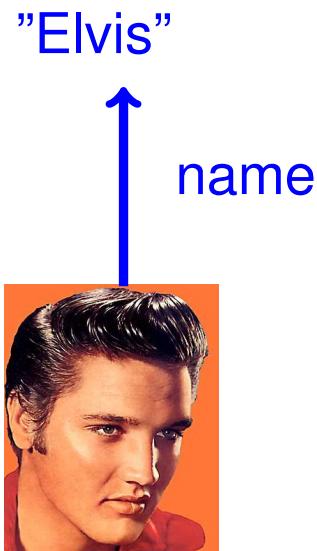

OWL and RDF are standard vocabularies for the linking.

Match classes, entities, & relations

There are numerous approaches for KB linking. We show here
F. Suchanek, S. Abiteboul, P. Senellart:
“PARIS: Probabilistic Alignment of Relations, Instances, and Schema”
VLDB 2012

Match classes, entities, & relations

1. Match literals

(either by identity or with a similarity function)

Identical literals are equivalent by definition.

Match classes, entities, & relations

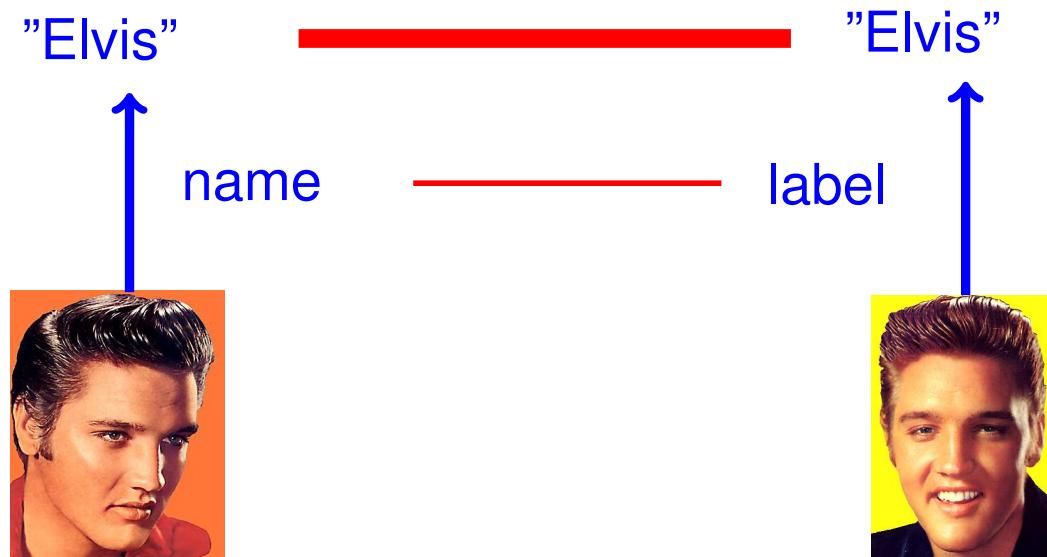

1. Match literals

Match classes, entities, & relations

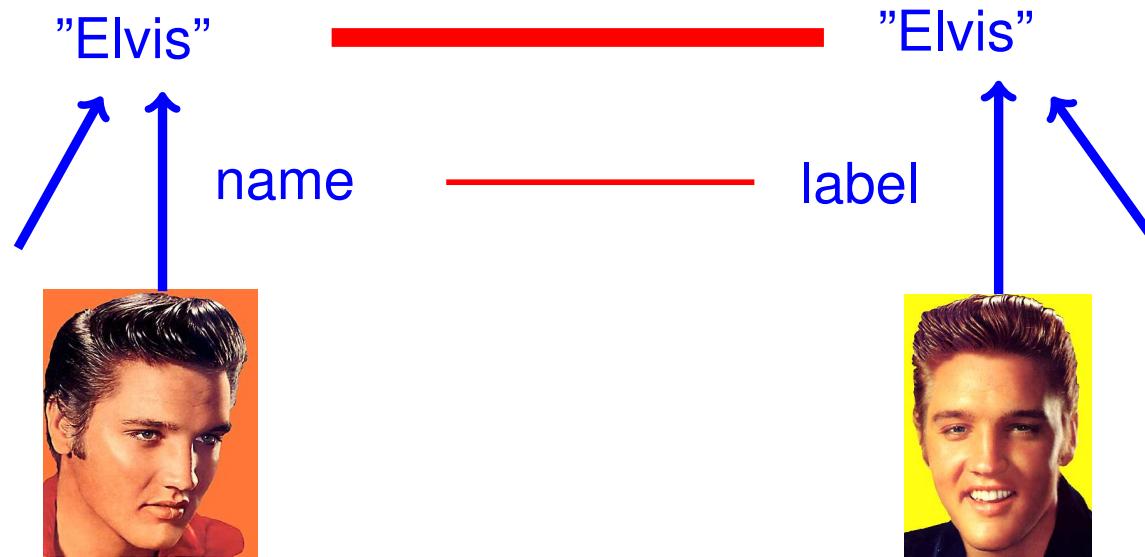

2. Assume small equivalence of all relations

Match classes, entities, & relations

2. Assume small equivalence of all relations

Match classes, entities, & relations

What about matching the entities?

What does it mean that both Elvises share the same name?

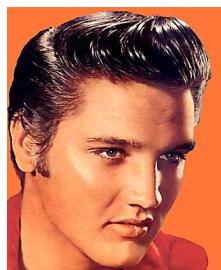

What does it mean if both Elvises share the same birth year?

Def: Local Functionality

The **local functionality** of a relation r and a subject s is one over the number of its objects.

$$fun(x, r) = \frac{1}{\#y:r(x,y)}$$

孙瑞猜想：目的是算重要程度

$$fun(Elvis, \text{born}) = 1$$
$$fun(Elvis, \text{sang}) = 0.$$

Def: Functionality

The **functionality** of a relation r is the harmonic mean of the local functionalities for all its subjects.

$$fun(r) = HM_x fun(x, r)$$

It is equivalent to the number of its subjects divided by the number of its facts:

(corrected sentence)

$$fun(r) = \frac{\#x: \exists y: r(x,y)}{\#x, y: r(x,y)}$$

Example:

$fun(hasBirthDate) = 1$ (exactly one object per subject)

$fun(hasDeathDate) = 1$ (at most one object per subject)

$fun(hasNationality) = 0.9$ (few objects per subject)

$fun(hasFriend) = 0.2$ (several objects per subject)

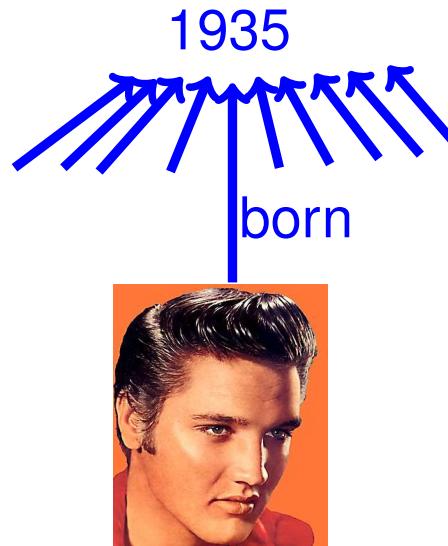

Def: Inverse Functionality

The **inverse local functionality** for an object y and a relation r is the number of subjects x with $r(x, y)$.

$$ifun(r, y) = \frac{1}{\#x:r(x,y)}$$

对象y和关系r的逆局部函数是具有 $r(x, y)$ 的主题x的数量。

孙瑞猜想：越大越好，代表越有区分度。。

$$ifun(name, Elvis) = \frac{1}{2}$$

$$ifun(born, Elvis) = \frac{1}{10}$$

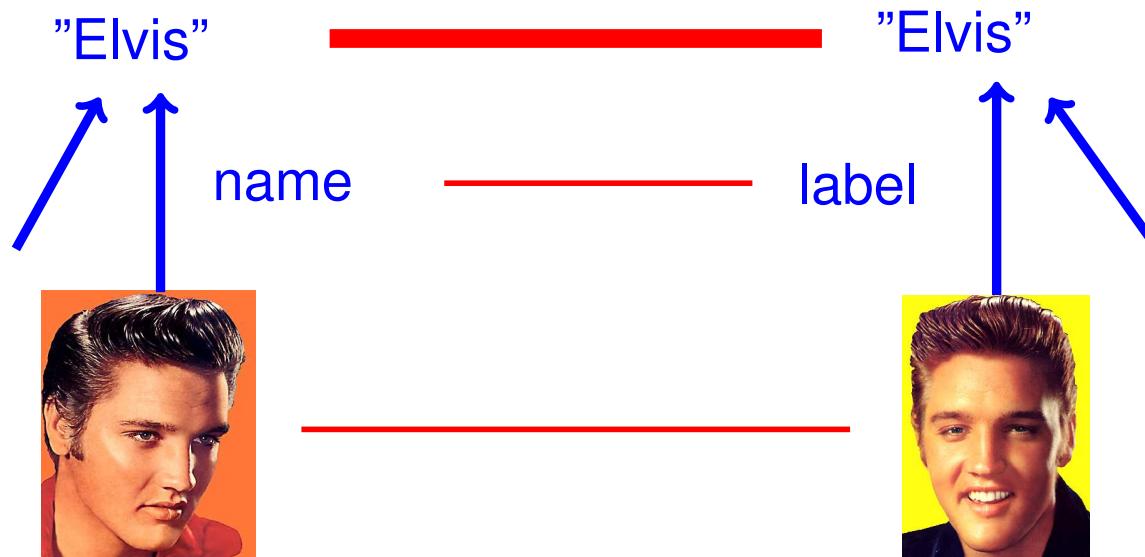

关系r的逆函数类似于功能来定义。

The **inverse functionality** of a relation r is defined analogously to the functionality.

$$ifun(name) = 0.9$$

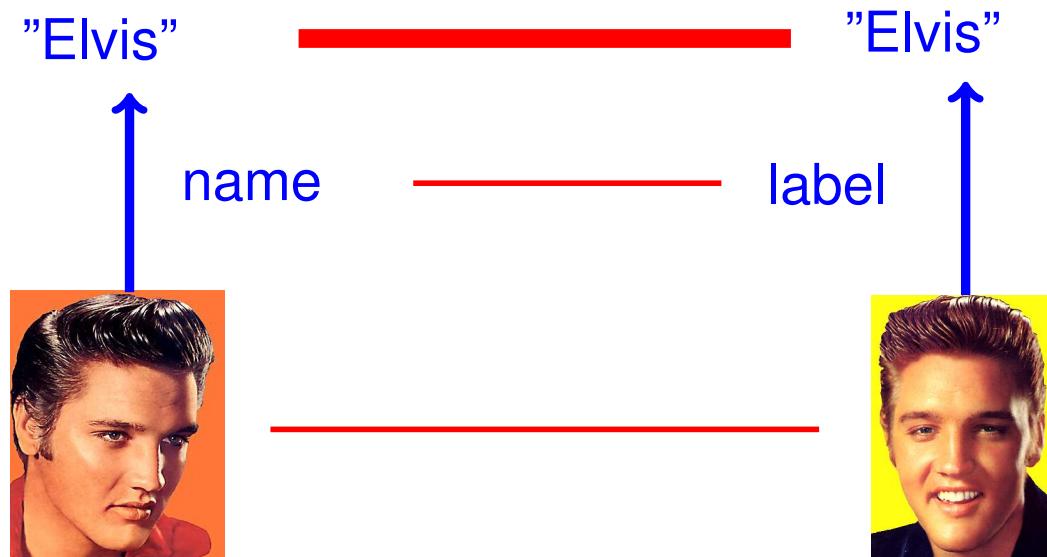

$$ifun(born) = 0.1$$

Match classes, entities, & relations

3. If subjects share a relation that is highly inverse functional, and the object is matched, then match the subjects.

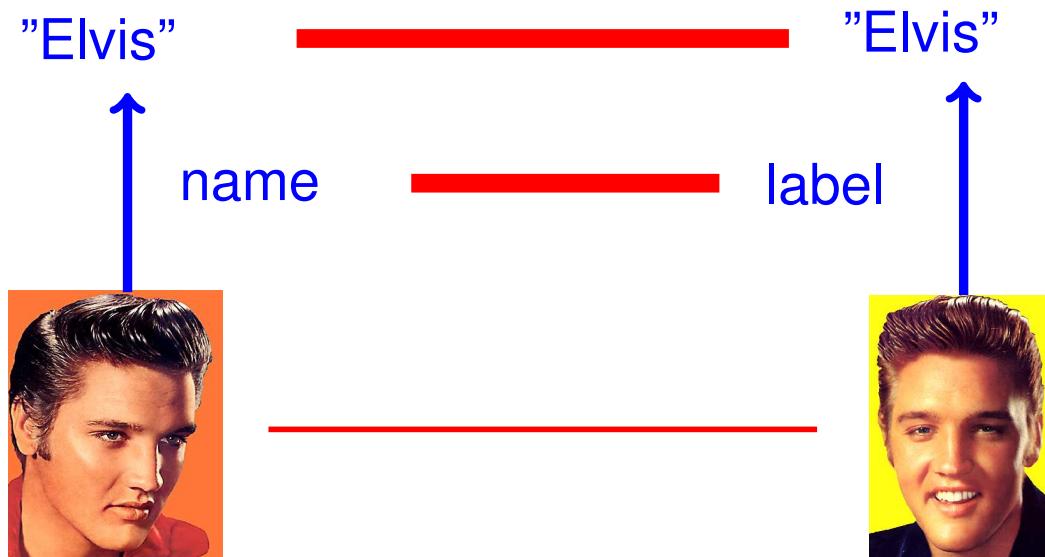

Match classes, entities, & relations

4. If relations share many pairs, increase their match

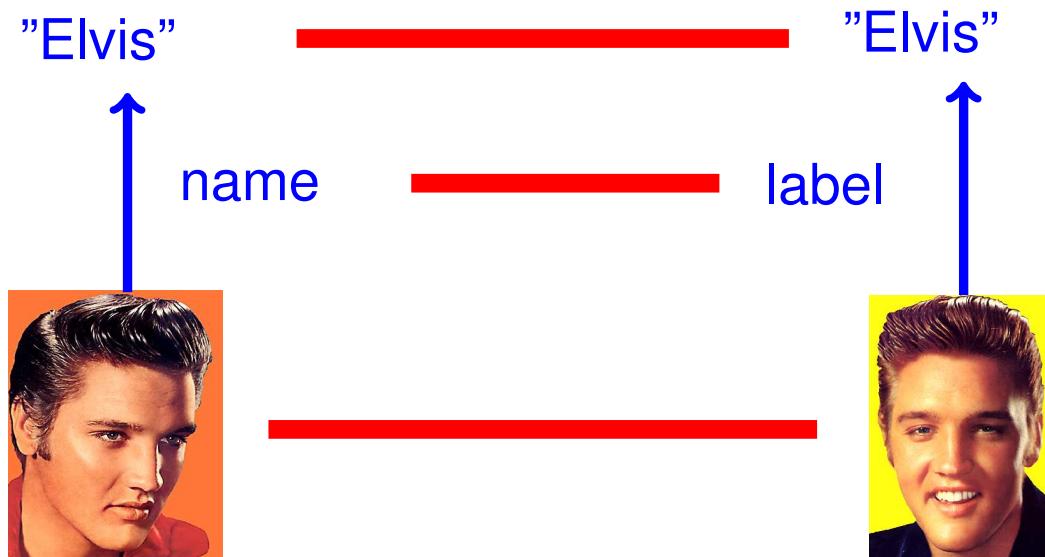

孙瑞猜想：若很多东西都用到（共享）某个relationship，就说明这个relationship的可信度很高，比如说：每个人都用名字，即可信度高

Match classes, entities, & relations

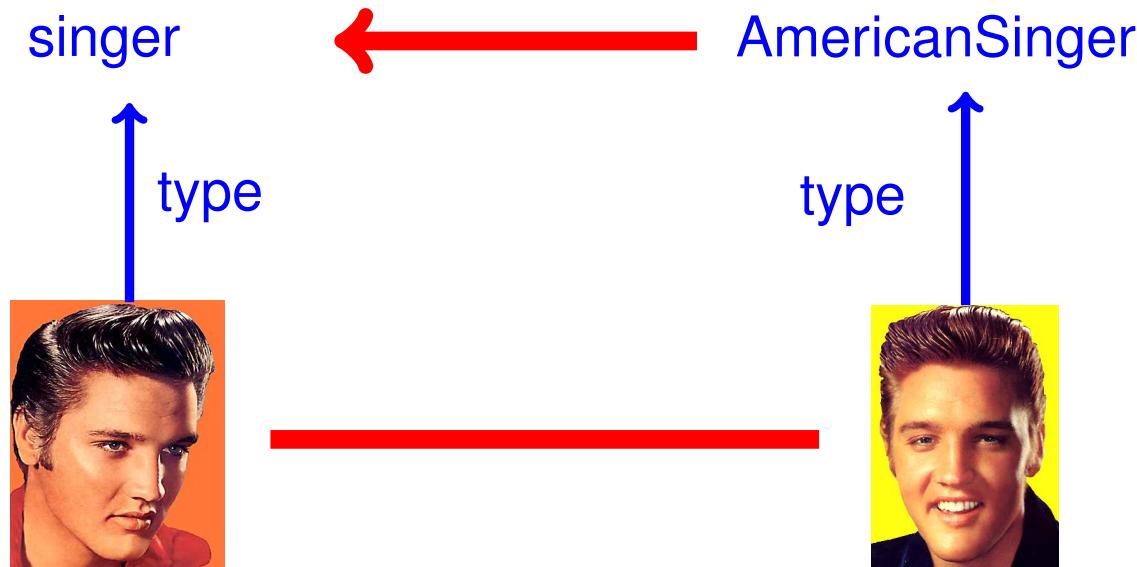

4. If relations share many pairs,
increase their match

Match classes, entities, & relations

5. Iterate

Match classes, entities, & relations

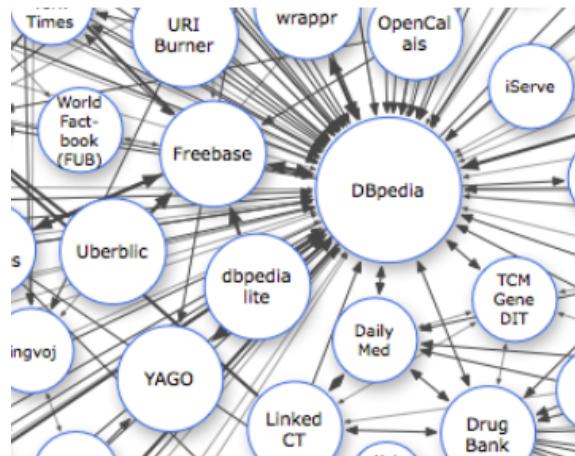

6. Compute class subsumption
(based on the overlap of entities)

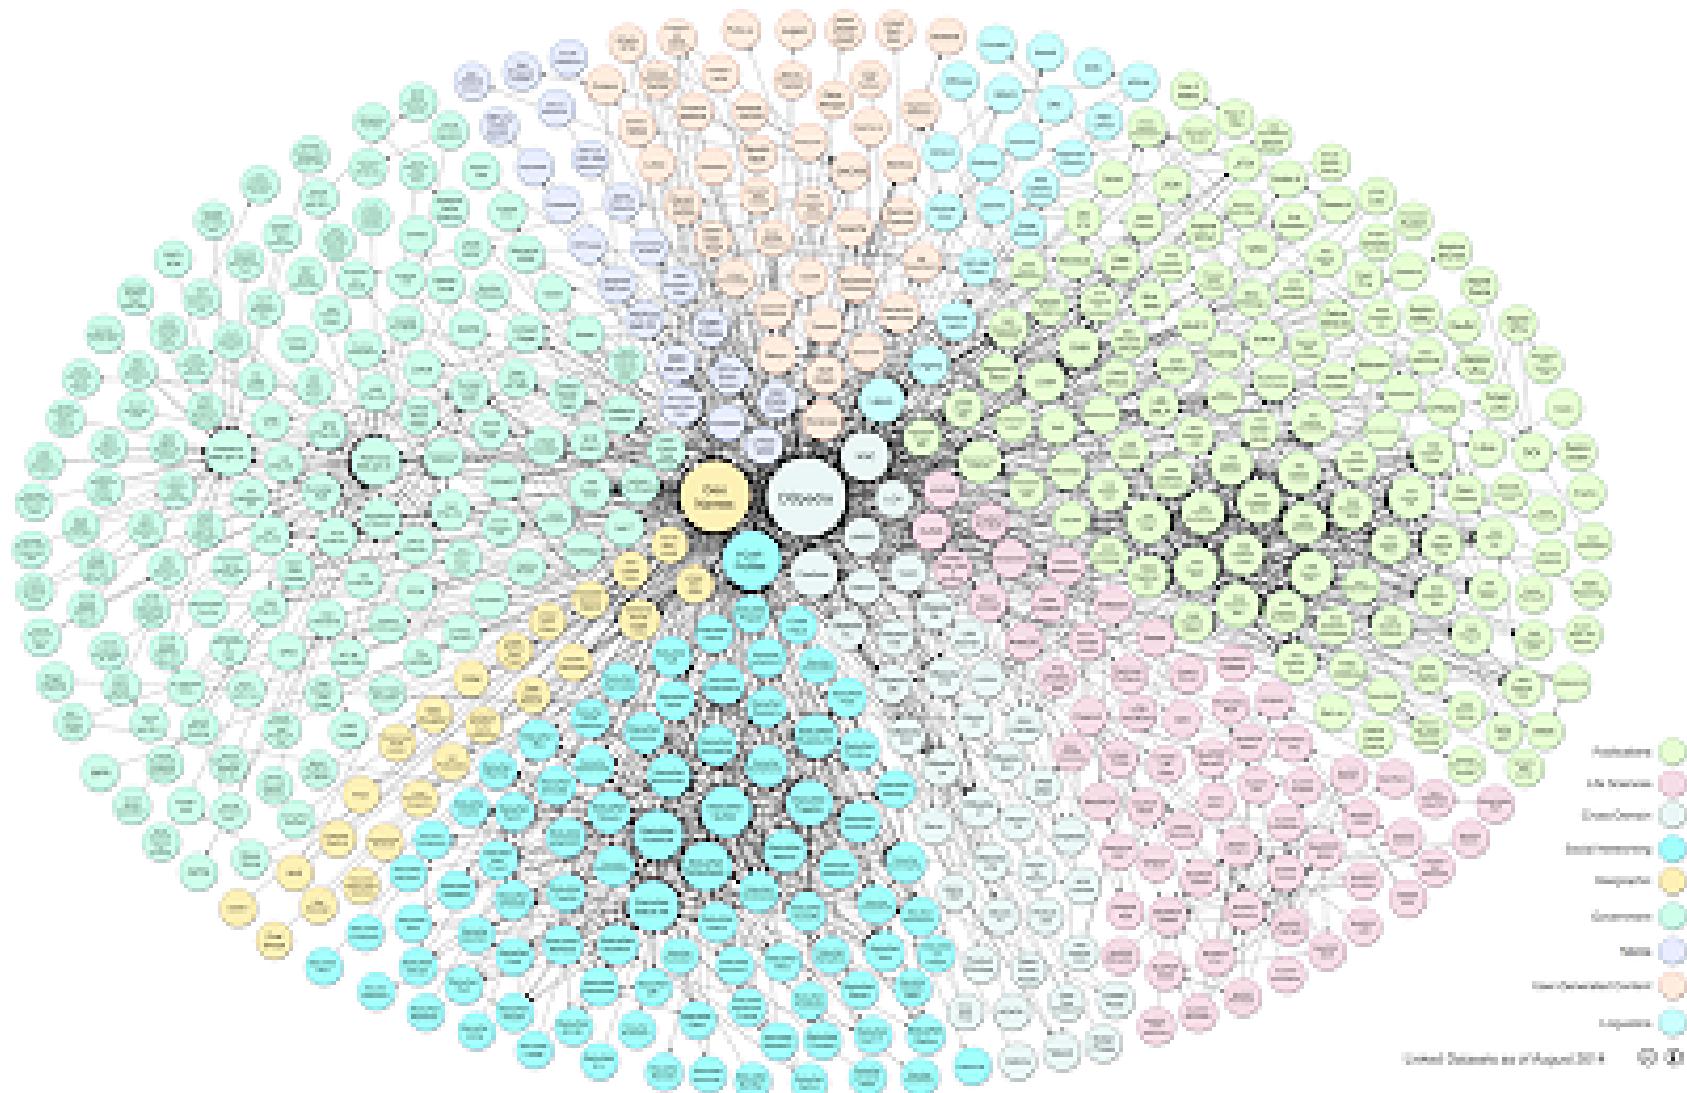

Numerous other approaches exist (e.g. based on name similarity).

Def: Linked Open Data Project

The goal of W3C's Linked Open Data Project is to publish and link open KBs.

The Linked Open Data Project

As of 2014: 1000 Kbs

>details

The Linked Open Data Project

Existing KBs include

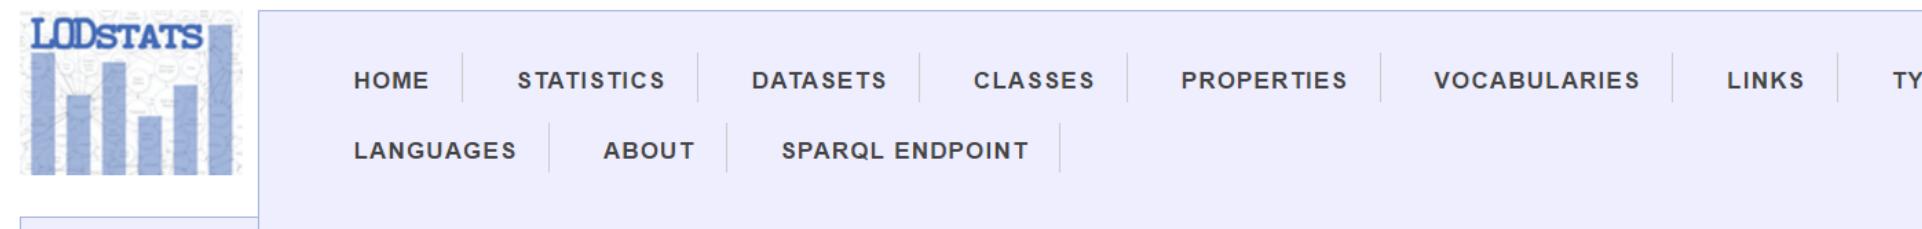

- US census data
 - BBC music database
 - Gene ontologies
 - DBpedia general knowledge, + YAGO, + Cyc etc.
 - UK government data
 - geographical data in abundance
 - national library catalogs (USA, Germany etc.)
 - publications (DBLP)
 - commercial products
 - all Pokemons
- ...and many more

[>details](#)

DataHub lists public KBS

The screenshot shows the DataHub website interface. At the top is a dark header bar with the DataHub logo on the left, which includes a stylized square icon and the text "datahub" in lowercase, followed by the tagline "The easy way to get, use and share data". To the right of the logo are three navigation links: "Datasets" (which is highlighted in a light gray box), "Organizations", and "About". Below the header, the main content area has a light gray background. On the left side, there is a sidebar titled "Organizations" with a dropdown arrow icon. It contains a list of organizations with their names and dataset counts: "Global (3433)", "London Datastore Ar... (612)", "Senegal (548)", "Open Hampton Roads (531)", and "Canada (514)". To the right of the sidebar is a search bar with the placeholder text "Search...". Above the search bar is a large, dark button with a white plus sign and the text "Add Dataset". At the bottom of the main content area, the text "10,632 datasets found" is displayed in a large, bold, black font.

LOD Stats shows KB Statistics

Cumulative numbers

9960 datasets

130,502,164,357 triples from **2740 datasets** (176,593,214 triples from **2612 dumps**, 130,325,571,143 from **145 datasets via SPARQL**)

Problems with **7203 datasets** (72.4%): **6804 dumps having errors, 399 SPARQL endpoints with errors**

Summary: Linked Data

The Linked Data project aims to make KBs machine-accessible through

- Public RDF KBs on the Internet
- Dereferenceable/Cool URIs
- Links between the KBs

The Semantic Web

- Knowledge Representation
- URIs
- Standard Vocabularies

Def: RDFa

RDFa is a syntax to annotate HTML pages with RDF.

RDFa Lite

<div>

Martin Thunderbird

Researcher in Rock'N'Roll Music of 1935-1977

Memphis, Tennessee

</div>

>details

Defining the vocabulary

All local names in an HTML node live in the namespace given by “vocab”.

```
<div vocab="http://schema.org/">  
    Martin Thunderbird<br>  
    Researcher in Rock'N'Roll Music of 1935-1977<br>  
    Memphis, Tennessee  
</div>
```

>details

Defining the subject

All properties in the HTML node take as subject the entity given by “resource”.

```
<div vocab="http://schema.org/"
```

```
  resource="http://martin.org/me">
```

```
    Martin Thunderbird<br>
```

```
    Researcher in Rock'N'Roll Music of 1935-1977<br>
```

```
    Memphis, Tennessee
```

```
</div>
```

>details

Defining a type

The type of the subject is given by “typeOf”.

```
<div vocab="http://schema.org/"  
resource="http://martin.org/me" typeOf="Person">  
Martin Thunderbird<br>  
Researcher in Rock'N'Roll Music of 1935-1977<br>  
Memphis, Tennessee  
</div>  
  
<http://martin.org/me> rdf:type <http://schema.org/Person> .
```

>details

Defining a fact with a literal object

A tag with “property” defines a fact between subject and that tag’s text value.

```
<div vocab="http://schema.org/"  
resource="http://martin.org/me" typeOf="Person">  
  <span property="name">Martin</span><br>  
  Researcher in Rock'N'Roll Music of 1935-1977<br>  
  Memphis, Tennessee  
</div>  
  
<http://martin.org/me> <http://schema.org/name> "Martin" .
```

>details

Defining a fact with an entity object

A tag with “property” and “resource” defines a fact between subject and URI.

```
<div vocab="http://schema.org/"  
      resource="http://martin.org/me" typeOf="Person">  
  <span property="name">Martin Th</span><br>  
  <span property="homeLocation" resource=  
        "http://yago.org/Memphis">Memphis</span>  
</div>
```

```
<http://martin.org/me> <http://schema.org/homeLocation>  
  <http://yago.org/Memphis> .
```

>details

Nested facts

A tag with “property” and “typeof” creates a new entity.

...

```
<span property="address" typeOf="postalAddress"
<span property=streetAddress>42 Elvis Rd</span>
<span property=postalCode>12345</span>
</span>
```

```

RDFa friends/foes

Standards that are similar to RDFa are

- Microformats
- Microdata

RDFa embeds facts into HTML

Advantages:

- Grass root appeal
(everybody can start annotating pages)
- No data duplication
(all data in one file)
- Publisher independence
(everybody can use his own attributes)

RDFa Example
